Chapter 2 - Velocity, acceleration and scalar angular velocity

Solution. 2.3 Given that acceleration is constant then the instant acceleration a is equal to the average acceleration a_{avg} so assuming that we start from t=0 at x=0 and the final velocity is v then we have that

$$a = \frac{\Delta v}{\Delta t}$$

$$a = \frac{v - u}{t - 0}$$

$$at = v - u$$

$$v = u + at$$
(1)

Now integrating both sides of the equation with respect to t:

$$\int_0^t v dt = \int_0^t u dt + \int_0^t at dt$$

$$\int_0^t dx = \int_0^t u dt + \int_0^t at dt$$

$$x(t) - x(0) = ut + \frac{1}{2}at^2$$

$$x = ut + \frac{1}{2}at^2$$
(2)

From (1) we get that $t = \frac{v-u}{a}$ and replacing in (2) we have

$$x = u\frac{(v-u)}{a} + \frac{1}{2}a\frac{(v-u)^2}{a^2}$$

$$ax = uv - u^2 + \frac{1}{2}(v^2 - uv + u^2)$$

$$ax = \frac{v^2}{2} - \frac{u^2}{2}$$

$$2ax = v^2 - u^2$$
$$v^2 = u^2 + 2ax$$

Finally if we replace $t=11.4~\mathrm{s}$ and $v=116~\mathrm{mph}=168.96~\mathrm{ft/s}$ in (1) we get that $a=14.82~\mathrm{ft/s^2}$ but then if we replace the same values in (2) assuming $x=0.25~\mathrm{mi}=1320~\mathrm{ft}$ we get that $a=20.31~\mathrm{ft/s^2}$ which means that the acceleration is not constant because otherwise it must satisfy both equations.

Solution. 2.6 First we calculate the following

$$r = be^{\Omega t}$$
 $\theta = \Omega t$
 $\dot{r} = b\Omega e^{\Omega t}$ $\dot{\theta} = \Omega$
 $\ddot{r} = b\Omega^2 e^{\Omega t}$ $\ddot{\theta} = 0$

Now replacing in $\mathbf{v} = \dot{r}\hat{\mathbf{r}} + (r\dot{\theta})\hat{\boldsymbol{\theta}}$ and in $\mathbf{a} = (\ddot{r} - r\dot{\theta}^2)\hat{\mathbf{r}} + (r\ddot{\theta} + 2\dot{r}\dot{\theta})\hat{\boldsymbol{\theta}}$ we get that

$$\mathbf{v} = b\Omega e^{\Omega t} \hat{\mathbf{r}} + (be^{\Omega t}\Omega)\hat{\boldsymbol{\theta}}$$

And

$$\mathbf{a} = (b\Omega^2 e^{\Omega t} - b\Omega^2 e^{\Omega t})\hat{\mathbf{r}} + (be^{\Omega t}0 + 2b\Omega^2 e^{\Omega t})\hat{\boldsymbol{\theta}}$$
$$= 2b\Omega^2 e^{\Omega t}\hat{\boldsymbol{\theta}}$$

Then,

$$|v| = \sqrt{2}b\Omega^2 e^{\Omega t}$$
$$|a| = 2b\Omega^2 e^{\Omega t}$$

So by using the formula for the dot product we compute $cos(\alpha) = \frac{a \cdot b}{|a||b|}$ as

$$cos(\alpha) = \frac{2b^2 \Omega^3 e^{2\Omega t}}{(\sqrt{2}b\Omega^2 e^{\Omega t})(2b\Omega^2 e^{\Omega t})}$$
$$= \frac{1}{\sqrt{2}}$$

Finally, this means that $\alpha = \pi/4$.

Solution. 2.9 From $\mathbf{v} = \dot{r}\hat{\mathbf{r}} + (r\dot{\theta})\hat{\boldsymbol{\theta}}$ we calculate the velocity vector where

$$\dot{r} = \frac{2b}{\tau} - \frac{2b}{\tau^2}t$$

$$\dot{\theta} = \frac{1}{\tau}$$

Then the velocity vector is

$$oldsymbol{v} = rac{2b}{ au^2}(au - t)oldsymbol{\hat{r}} + rac{bt}{ au^3}(2 au - t)oldsymbol{\hat{ heta}}$$

Now let's compute $|v|^2$

$$|\mathbf{v}|^2 = \frac{4b^2}{\tau^4} \tau^2 - \frac{8b^2\tau}{\tau^4} t + \frac{4b^2}{\tau^4} t^2 + \frac{4b^2\tau^2}{\tau^6} t^2 - \frac{4b^2\tau}{\tau^6} t^3 + \frac{b^2}{\tau^6} t^4$$

$$= \frac{4b^2}{\tau^2} - \frac{8b^2}{\tau^3} t + \frac{8b^2}{\tau^4} t^2 - \frac{4b^2}{\tau^5} t^3 + \frac{b^2}{\tau^6} t^4$$

$$= \frac{b^2}{\tau^6} (t^4 - 4\tau t^3 + 8\tau^2 t^2 - 8\tau^3 t + 4\tau^4)$$

To find the maximum value of |v| let's consider the time derivative of $|v|^2$

$$\frac{d|\mathbf{v}|^2}{dt} = \frac{b^2}{\tau^6} (4t^3 - 12\tau t^2 + 16\tau^2 t - 8\tau^3)$$

$$= \frac{4b^2}{\tau^6} (t^3 - 3\tau t^2 + 4\tau^2 t - 2\tau^3)$$

$$= \frac{4b^2}{\tau^6} (t^3 - \tau t^2 - 2\tau t^2 + 2\tau^2 t + 2\tau^2 t - 2\tau^3)$$

$$= \frac{4b^2}{\tau^6} (t(t^2 - 2\tau t + 2\tau^2) - \tau(t^2 - 2\tau t + 2\tau^2))$$

$$= \frac{4b^2}{\tau^6} (t - \tau)(t^2 - 2\tau t + 2\tau^2)$$

Since $t^2 - 2\tau t + 2\tau^2$ can be written as $\tau^2 + (t - \tau)^2$ we see that this term no matter the value of t is always positive so

$$\frac{d|\mathbf{v}|^2}{dt} = \begin{cases} <0 & \text{if } t < \tau \\ = 0 & \text{if } t = \tau \\ > 0 & \text{if } t > \tau \end{cases}$$

Hence |v| achives a minimum value when $t = \tau$ so

$$|\boldsymbol{v}|^2 = \frac{b^2}{\tau^6} \tau^4$$
 $|\boldsymbol{v}| = \frac{b}{\tau}$

Finally the acceleration is given by

$$a = (-\frac{2b}{\tau^2} - \frac{2b}{\tau^3}t + \frac{b}{\tau^4}t^2)\hat{r} + (\frac{4b}{\tau^2}(1 - \frac{t}{\tau}))\hat{\theta}$$

and when $t = \tau$ we have that

$$oldsymbol{a} = -rac{3b}{ au^2} oldsymbol{\hat{r}}$$

Solution. 2.10 The Lion's velocity can be calculated as

$$\boldsymbol{v} = \dot{r}\hat{\boldsymbol{r}} + r\dot{\theta}\hat{\boldsymbol{\theta}}$$

So calculating the speed of the Lion knowing that $\dot{\theta}$ is the angular velocity and can be written as $\dot{\theta} = \frac{u}{a}$ where u is the velocity of Daniel and a is the radius then we get that

$$U^2 = \dot{r}^2 + (r\dot{\theta})^2$$
$$= \dot{r}^2 + (\frac{ru}{a})^2$$

which can be re-written as

$$\begin{split} \dot{r}^2 &= U^2 - (\frac{ru}{a})^2 \\ &= \frac{u^2}{a^2} (\frac{U^2 a^2}{u^2} - r^2) \end{split}$$

This ODE can be solved as follows

$$\dot{r} = \frac{u}{a} \sqrt{\frac{U^2 a^2}{u^2} - r^2}$$

$$\frac{dr}{dt} = \frac{u}{a} \sqrt{\frac{U^2 a^2}{u^2} - r^2}$$

$$\int \frac{dr}{\sqrt{\frac{U^2 a^2}{u^2} - r^2}} = \int \frac{u}{a} dt$$

$$\int \frac{dr}{\sqrt{\frac{U^2 a^2}{u^2} - r^2}} = \frac{ut}{a}$$

$$\sin^{-1}(\frac{ur}{Ua}) + C = \frac{ut}{a}$$

the constant of integration C can be determined by knowing that r=0 when t=0 then C=0 and therefore

$$r = \frac{Ua}{u}sin(\frac{ut}{a})$$

For $t=\pi a/2u$ we get that r=Ua/u and if $U\geq u$ then $\frac{U}{u}\geq 1$ so $r=\frac{Ua}{u}\geq a$ which means that the Lion will caught Daniel in $t=\pi a/2u$ if $U\geq u$. In order to recognize the equation for r as a circle we multiply both sides by r so we get that

$$r^2 = \frac{Ua}{u}r\sin(\frac{ut}{a})$$

now knowing that $r^2 = x^2 + y^2$ and that $r \sin(\frac{ut}{a}) = y$ then

$$x^{2} + y^{2} = \frac{Ua}{u}y$$

$$y^{2} - \frac{Ua}{u}y = -x^{2}$$

$$y^{2} - \frac{2Ua}{2u}y + (\frac{Ua}{2u})^{2} = -x^{2} + (\frac{Ua}{2u})^{2}$$

$$(y - \frac{Ua}{2u})^{2} = -x^{2} + (\frac{Ua}{2u})^{2}$$

$$x^{2} + (y - \frac{Ua}{2u})^{2} = (\frac{Ua}{2u})^{2}$$

which is an equation of a circle with center at $(0, \frac{Ua}{2u})$ and radius $\frac{Ua}{2u}$. When U=u we get that the Lion's path is described by

$$x^{2} + (y - \frac{a}{2})^{2} = (\frac{a}{2})^{2}$$

which is a circle with center at $(0, \frac{a}{2})$ and radius $\frac{a}{2}$.

Solution. 2.11 We know that the velocity in a general form can be written as

$$\boldsymbol{v} = v\boldsymbol{t}$$

where t is the unit tangential vector, and the acceleration can be written as

$$\boldsymbol{a} = \frac{dv}{dt}\boldsymbol{t} + \frac{v^2}{\rho}\boldsymbol{n}$$

where n is the unit normal vector, since v is constant then $\frac{dv}{dt} = 0$ so the acceleration can be written as

$$a = \frac{v^2}{\rho} n$$

which only has the normal component, therefore the acceleration is perpendicular to the velocity. \Box

Solution. 2.14 Knowing that

$$r = b \cosh(\Omega t)$$

then

$$\dot{r} = b\Omega \sinh(\Omega t)$$

$$\ddot{r} = b\Omega^2 \cosh(\Omega t)$$

so from the polar velocity equation we have that

$$\mathbf{v} = \dot{r}\hat{\mathbf{r}} + r\dot{\theta}\hat{\boldsymbol{\theta}}$$

$$= b\Omega \sinh(\Omega t)\hat{\mathbf{r}} + b\Omega \cosh(\Omega t)\hat{\boldsymbol{\theta}}$$

$$= b\Omega (\sinh(\Omega t)\hat{\mathbf{r}} + \cosh(\Omega t)\hat{\boldsymbol{\theta}})$$

and the speed of the particle is then

$$|v|^2 = b^2 \Omega^2 \sinh^2(\Omega t) + b^2 \Omega^2 \cosh^2(\Omega t)$$
$$= b^2 \Omega^2 \cosh(2\Omega t)$$

Finally, the acceleration is derived as follows

$$\mathbf{a} = (\ddot{r} - r\dot{\theta}^2)\hat{\mathbf{r}} + (r\ddot{\theta} + 2\dot{r}\dot{\theta})\hat{\boldsymbol{\theta}}$$

$$= [b\Omega^2 \cosh(\Omega t) - b\Omega^2 \cosh(\Omega t)]\hat{\mathbf{r}} + [0 + 2b\Omega^2 \sinh(\Omega t)]\hat{\boldsymbol{\theta}}$$

$$= 2b\Omega^2 \sinh(\Omega t)\hat{\boldsymbol{\theta}}$$

Therefore the acceleration direction is circumferential and is given by $\hat{\theta}$. \square

Solution. **2.18** As the graph shows P is at $(b\sin(\Omega t), 0)$ from there and by using Pythagoras theorem we can derive that Q is at $(0, \sqrt{a^2 - b^2 \sin^2(\Omega t)})$ then C, the center of the link, has coordinates given $(\frac{b}{2}\sin(\Omega t), \frac{\sqrt{a^2 - b^2 \sin^2(\Omega t)}}{2})$. If we now move the origin (0,0) to C then the coordinates of P are given by $(\frac{b}{2}\sin(\Omega t), -\frac{\sqrt{a^2 - b^2 \sin^2(\Omega t)}}{2})$ so we have that the sine of the angle between the link and the negative Y-axis is given by

$$\sin(\theta) = \frac{\frac{b}{2}\sin(\Omega t)}{\frac{a}{2}}$$
 so $\theta = \sin^{-1}\left(\frac{b\sin\Omega t}{a}\right)$

now derivating this expression with respect to t we get the Angular velocity as

$$\dot{\theta} = \omega = \frac{b\Omega \cos(\Omega t)}{\sqrt{a^2 - b^2 \sin^2(\Omega t)}}$$

Finally, since we know the coordinates for C we can calculate the velocity as

$$oldsymbol{v} = rac{\Omega b}{2} \cos(\Omega t) oldsymbol{i} - rac{\Omega b^2 \sin(\Omega t) \cos(\Omega t)}{2\sqrt{a^2 - b^2 sin^2(\Omega t)}} oldsymbol{j}$$

so now we can calculate the speed for the link center by

$$|v|^{2} = \frac{\Omega^{2}b^{2}}{4}\cos^{2}(\Omega t) + \frac{\Omega^{2}b^{4}\sin^{2}(\Omega t)\cos^{2}(\Omega t)}{4(a^{2} - b^{2}\sin^{2}(\Omega t))}$$

$$= \frac{\Omega^{2}b^{2}}{4}\cos^{2}(\Omega t)\left(1 + \frac{b^{2}\sin^{2}(\Omega t)}{a^{2} - b^{2}\sin^{2}(\Omega t)}\right)$$

$$= \frac{\Omega^{2}b^{2}}{4}\cos^{2}(\Omega t)\left(\frac{a^{2}}{a^{2} - b^{2}\sin^{2}(\Omega t)}\right)$$

$$= \frac{\Omega^{2}b^{2}a^{2}\cos^{2}(\Omega t)}{4(a^{2} - b^{2}\sin^{2}(\Omega t))}$$

Finally

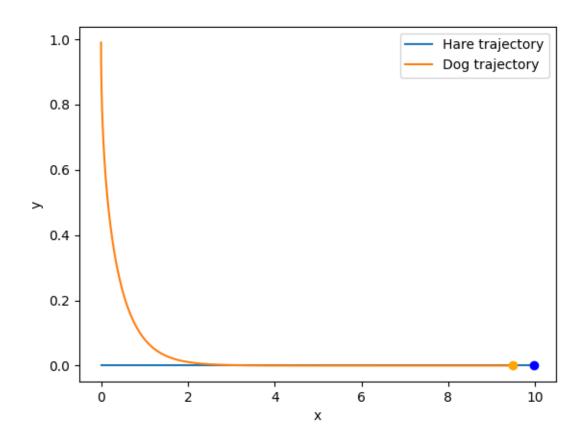

$$|v| = \frac{\Omega ba \cos(\Omega t)}{2\sqrt{a^2 - b^2 sin^2(\Omega t)}}$$

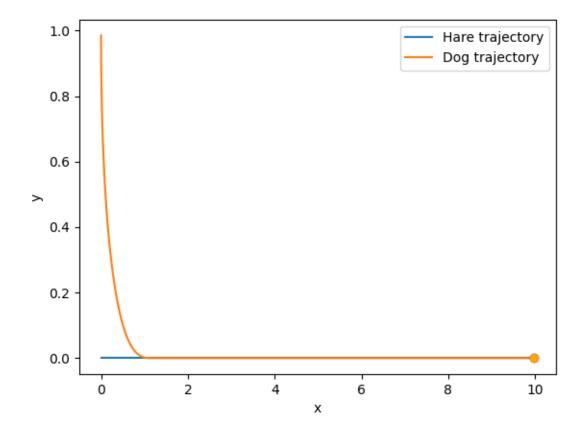

Solution. 2.22

(i) Solving the equations given by computational means (Runge-kutta method)

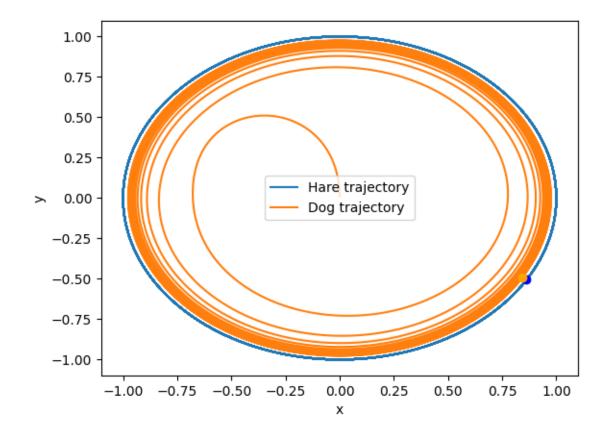

$$\dot{X} = -\frac{v^D X}{\sqrt{X^2 + Y^2}} - v_x^H$$
 $\dot{Y} = -\frac{v^D Y}{\sqrt{X^2 + Y^2}} - v_y^H$

when $v^D = v^H$ we get the following plot

(ii) Now we solve the equations for the case where the Hare has a circular trajectory when $v^D=v^H$ we get the following plot

but if $v^D > v^H$
